Societal vs Individual Risk of Death in Europe

**Societal risk** is represented as the risk of death per million total population. **Individual risk** is represented as the risk of death per million exposed to a particular hazard. Bubble size represents the relative risk to an individual. By way of example, the bubbles representing deaths due to smoking exposure and illicit drug use are a similar size because the risk of death due to exposure to smoking is similar to that for an illicit drug user. Smoking poses a greater risk to society simply because vastly more citizens die due to exposure to smoking than illicit drug use.
